GitHub Multi-Account Setup & Management Guide

Personal Account Isolation (AntiGravity) vs. Company Account (VS Code)

This guide details how your Mac is configured to seamlessly run both your Company GitHub account (in VS Code) and your Personal GitHub account (in Google AntiGravity) without any cross-account conflicts or risk of leaking credentials.

1. Core Concept & Isolation Architecture

- **Work Isolation:** Company work remains untouched in VS Code and uses your company credentials stored in macOS Keychain.
- **Personal Isolation:** All projects inside ~/Documents/Google_AntiGravity/ automatically use your personal identity and personal SSH key.
- **Author Identity:** Personal author identity is locked to shoaibmumtaz <shoaibmumtaz28@gmail.com>.
- **URL Translation:** Even if you paste an HTTPS GitHub link, Git translates it to SSH so macOS Keychain never tries to log in with your company account.

2. Active Configuration Summary

- **Dedicated SSH Key:** ~/.ssh/id_ed25519_personal (Added to GitHub account: shoaibmumtaz)
- **Global Git Rule:** ~/.gitconfig contains includeIf for ~/Documents/Google_AntiGravity/
- **Dedicated Config:** ~/.gitconfig-antigravity contains user details, SSH command, and URL rules.
- **Local Backup System:** ./backup.sh script keeps versioned local zips and bundle snapshots in _Backups/.

3. Step-by-Step: Connecting a Project to GitHub

When you create a new repository on github.com (under shoaibmumtaz) and want to link it:

```
# 1. Add your repository remote URL (HTTPS or SSH both work):
git remote add origin https://github.com/shoaibmumtaz/my-repo.git

# 2. Push your main branch to GitHub:
git push -u origin main
```

4. Step-by-Step: Verifying Current Account & Remotes

To check which identity and remote any repository is currently configured with:

```
# Check commit author name & email:
git config user.name
git config user.email

# Check where the repository pushes to:
git remote -v
```

5. Step-by-Step: Changing Settings for a Single Project

If you ever need to override the name, email, or remote for just one project:

```
# Set a custom author name or email for ONLY this repository:
git config user.name "Your Name"
git config user.email "your-email@example.com"

# Change the remote GitHub repository URL:
git remote set-url origin https://github.com/shoaibmumtaz/new-repo.git

# Disconnect from GitHub entirely (reverts to local-only):
git remote remove origin
```

6. Step-by-Step: Managing or Modifying the Automatic Rule

Your personal settings are stored cleanly in dedicated config files:

```
# View your active global Git settings:
git config --global --list

# Edit your personal AntiGravity settings (email, key, etc.):
nano ~/.gitconfig-antigravity

# To disable the automatic folder rule completely in the future:
git config --global --unset "includeIf.gitdir:~/Documents/Google_AntiGravity/.path"
```

7. Local Backup Workflow Reminder

As defined in the project version control rules, local snapshots are created using:

```
./backup.sh "Describe what was changed"    # Creates local commit, tag & zip
./backup.sh list                           # Displays all timestamped backups
```
