GitHub Multi-Account Setup & Management Guide

Personal Account Isolation (AntiGravity) vs. Company Account (VS Code)

This guide explains how your Mac is configured to cleanly separate your Company GitHub account (in VS Code) from your Personal GitHub account (shoaibmumtaz, in Google AntiGravity), ensuring zero credential collisions.

1. Core Concept & Complete Account Isolation

- **Work Profile (VS Code):** Operates completely untouched, using your existing company credentials stored in macOS Keychain.
- **Personal Profile (AntiGravity):** Configured to strictly use your dedicated personal SSH key and personal author credentials.
- **Commit Author Identity:** Stamped as shoaibmumtaz <shoaibmumtaz28@gmail.com> for all personal project commits.
- **Automatic URL Routing:** Standard HTTPS or SSH GitHub URLs automatically translate to your personal SSH key.

2. Active Configuration Details

- **Dedicated SSH Key:** ~/.ssh/id_ed25519_personal (Linked to your personal GitHub: shoaibmumtaz)
- **SSH Host Config:** github-personal alias defined in ~/.ssh/config using IdentitiesOnly=yes.
- **Local Git URL Rewriting:** Translates https://github.com/ and git@github.com: to your personal key.
- **Local Backup System:** Enforces local commit messages without AI co-authors, and writes snapshots to _Backups/.

3. Step-by-Step: Connecting a Project to GitHub

When you create a repository on github.com (under shoaibmumtaz) and want to link your local code:

```
# 1. Add your repository remote URL (HTTPS or SSH both work automatically):
git remote add origin https://github.com/shoaibmumtaz/my-repo.git

# 2. Push your main branch to GitHub:
git push -u origin main
```

4. Step-by-Step: Verifying Current Account & Remotes

To check which identity and destination any repository is currently using:

```
# Check commit author name & email:
git config user.name
git config user.email

# Check where the repository pushes to:
git remote -v
```

5. Step-by-Step: Changing Settings for a Single Project

If you ever need to override the author, email, or remote for just one project:

```
# Set custom author details for ONLY this repository:
git config user.name "Your Name"
git config user.email "your-email@example.com"

# Change the remote GitHub repository URL:
git remote set-url origin https://github.com/shoaibmumtaz/new-repo.git

# Disconnect from GitHub entirely (reverts to local-only):
git remote remove origin
```

6. Step-by-Step: Testing or Modifying the Personal Setup

Your personal connection can be verified or modified anytime:

```
# Verify personal SSH connection directly with GitHub:
ssh -T git@github-personal

# View your active local repository Git settings:
git config --local --list

# View your active SSH host configuration:
cat ~/.ssh/config
```

7. Local Backup Workflow Reminder

As defined in the project version control rules, local snapshots are created using:

```
./backup.sh "Describe what was changed"    # Creates local commit, tag & zip
./backup.sh list                           # Displays all timestamped backups
```
